

Day 22: Turning previous theory into an actual environment.

Job Tracker:

Quickly, I don't want this to be part of the curriculum, as I need to keep learning. But some words that scared me were: Endpoint Management Tools (Intune and SCCM/MECM), and Veeam. Also more stuff that I didn't write down. For the future, I don't want this to be part of the curriculum. I'm working with a career coach block on the side to focus this, but I can definitely send results if you want to be synchronized.

Build / Start Windows Server VM

Get the ISO. Windows Server 2022 Evaluation ISO.

First Boot + Server Manager

Open: Server Manager.

Server Manager in Windows Server is the main control center for managing a Windows Server. It is like the dashboard for the server. A role is a major job that the server performs on the network. A Windows Server can become different types of servers depending on which roles you install. A feature is an extra capability or tool that supports the server, but it is usually not the server's main job. Local Server is the page in Server Manager that shows and controls settings for the server you are currently logged into.

I renamed the hostname to SRV-DC01. I did this through Server Manager -> Local Server -> Computer Name

A command for this would be: **Rename-Computer -NewName "SRV-DC01" -Restart**

Server Networking Check

Testing Powershell inside Windows Server. Run: **hostname**. Next: **ipconfig /all**. Next: **Get-NetIPAddress**. This command shows the IP address configuration. It tells you what IP addresses are assigned to your network adapters. \

Next: **Get-NetAdapter**. It shows the network adapters on a Windows Machine.

A Domain Controller should have a static IP address because other computers need to reliably find it. If its IP address keeps changing, the whole domain can break.

Understand the next build sequence...

1. Install Windows Server
2. Rename server to SRV-DC01

3. Configure static IP
4. Install AD DS role
5. Promote server to DC
6. Create domain
7. Configure DNS
8. Create users/group/OUs
9. Build Windows Client VM
10. Join client to domain
11. Apply Group Policy

To promote a server to a Domain Controller means: You take a normal Windows Server and turn it into an AD server that manages a domain.
